Correlating routing configuration changes with forwarding changes

- Determine if we can correlate routing conf changes with forwarding changes
- Routing configuration data obtained from a Tier-1 ISP
- Forwarding changes data obtained from own measurements
- We want to measure latency and path changes
- The goal is to detect eBGP events

Objectives Issues Results

Objectives Methodology

#### Objectives

- What measurements ?
  - Pings for latency
  - Traceroutes for path changes
- From where ?
  - Servers
  - Atlas probes
- To what ?
  - ISP's routers or some reachable IP

### About Atlas probes

- The probes are distributed world wide within plenty of ASes
- Currently about 1,500 probes are active
- In theory, perfect tool to measure a worldwide ISP
- We need to investigate the capacities and limitations of the Atlas probes

#### Material overview

- What do we have ?
  - Syslog of routers
  - CVS of configurations (RANCID, runs every two hours)
  - A list of thousands of reachable IPs in the neighborhood of the ISP
  - The list of all active Atlas probes
  - Three dedicated servers with ISP as transit provider (Seattle, Ashburn, Dallas)

## Organizing the data

#### • Prepare reachable IPs

- Perform traceroutes to each IP to have the exit POP
- Remove IPs for which there is only one hop in ISP
- Clusterize IPs with respect to their exit POP
- Prepare probes list
  - Take probes belonging to neighboring ASes
  - For all probes, perform a traceroute to some random reachable IPs
    - So that we can find the entry POP(s)
  - Clusterize the probes w.r.t. their entry POP

Objectives Issues Results

Objectives Methodology

## Measuring

- Main idea
  - For each probes cluster, select a probe
  - For each selected probe, for each IP cluster, select an IP
  - Ping or traceroute the IP from the probe
  - Repeat periodically

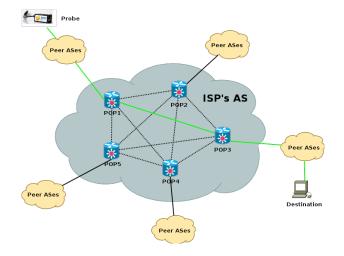

- Reminder: we want to detect eBGP events
- If we ping IPs in the neighborhood (IPs in the previously computed clusters)
  - Will detect unrelated events
  - No guarantee that the ping will go through ISP unless route is enforced by provider (localpref)
  - eBGP events can originate from farther in the as-path
  - The larger the distance from the target IP and the ISP, the more the noise will increase

Objectives Issues Results Ping issues Traceroute issues Probes issues

#### Ping issues

- If we ping ISP's border routers or direct neighbors
  - Difficult to detect eBGP events
  - But we can detect internal changes
  - We can also detect congested links due to eBGP events

#### Traceroute issues

- Big issue with standard traceroute: load balancers
- Standard techniques cannot properly handle equal-cost multipaths
- Leads to detection of non existent links

Objectives	Ping issues
Issues	Traceroute issues
Results	Probes issues

#### Traceroute issues

Source: http://www.paris-traceroute.net/about

Correlating routing configuration changes with forwarding changes

### Solution

- To solve this problem: paris-traceroute
- Use a Multipath Detection Algorithm
- Basic idea
  - Keep constant tuple (srcIP, srcPort, dstIP, dstPort)
  - Mark packets with fields not used to distinguish flows

	Objectives Issues Results	Ping issues <b>Traceroute issues</b> Probes issues
aris traceroute		

- Now we have a multipath-aware traceroute
- No longer affected by per-flow load balancers

Pa

#### Probes issues

- Most of probes do not use ISP as default provider
  - Some pairs (probe,IP) go through ISP
  - Most of these probes are more than 4 hops away from ISP (and more than 2 ASes away)
- High rate of path changes
  - The probes don't keep constant params for same dest across different traceroutes

	Objectives Issues Results	Ping issues Traceroute issues Probes issues	
Probes issues			

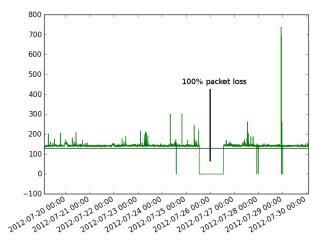

#### • Lot of noise in the ping data

- High stddev
- Huge latency peaks
- Missing data

# Traceroutes

## Two classes of traceroutes

- Internal path change
  - IGP change, LBs, link/router failure
- Exit POP change
  - eBGP change inside/outside ISP's AS, link/router failure

# Summary of the measurements

- Most events are IGP related
- Most of IGP events are link maintenances
- Less eBGP events than expected
- Most of eBGP events come from outside the ISP's AS and thus cannot be correlated with a configuration change
- Important events are easily detected even from a few sources
- Atlas probes need more work to be really usable in a project of this scale

# Conclusion

- Prefix-list updates can generate RTT peak on the router
- Interface shutdown causes permanent RTT change and internal path changes
- MPLS changes can cause RTT changes
- eBGP events (from the inside or the outside) cause exit POP change (unsurprisingly)

Objectives	Pings
Issues	Traceroutes
Results	Conclusion

Conclusion,

- IGP events easy to detect and correlate
- Significant eBGP events are easy to detect
- More difficult to correlate as it can originate from the outside

What was cool with the Atlas probes ?

- The JSON interface is very useful for scripting
- The ability to manually specify multiple probes for a single UDM
- Geographical dispersion of the probes
- Overall, the system works quite well
- The Atlas team for granting us credits :)

What can be improved ?

- Handling of bulk measurements (probes per UDM and UDMs per probe)
- Fetching results (interface response time)
- Paris-traceroute implementation
